Practical No 5

Aim: Analyse the packets provided in lab and solve the questions using Wireshark:

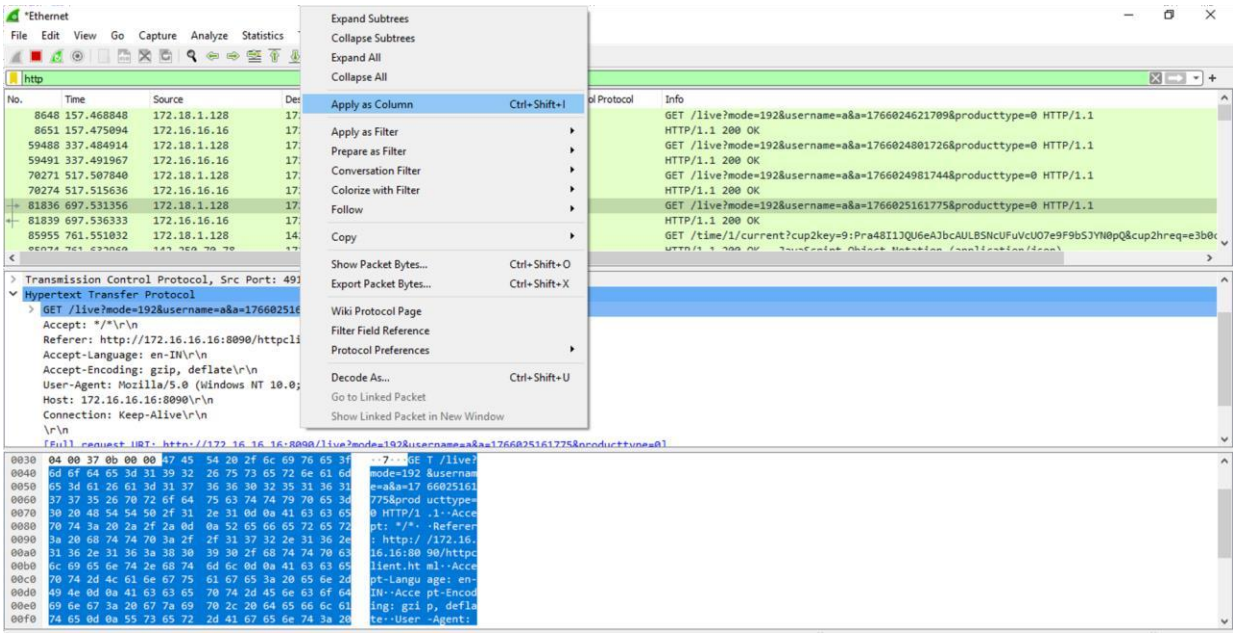
-What web server software is used by www.snopes.com? -About what cell phone problem is the client concerned?

-According to Zillow, what instrument will Ryan learn to play?

-How many web servers are running Apache? Steps:

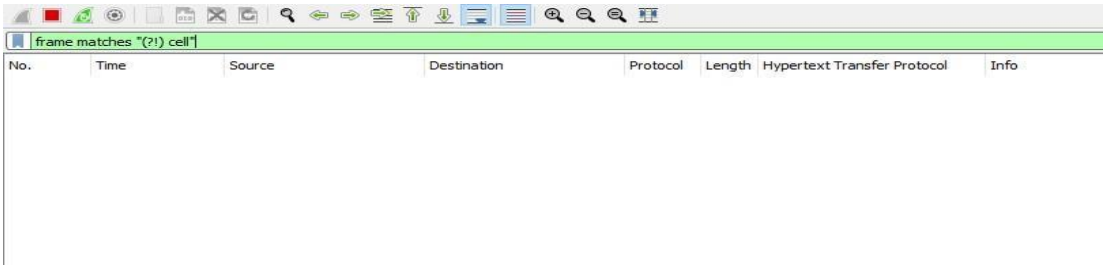
1. What web server software is used by www.snopes.com?

Analysis – The domain name be found from host header so we will set host header column where we will see all domain name. Select any HTTP request and expand the Hypertext Transfer Protocol then right click on Host header and then Apply as Column.



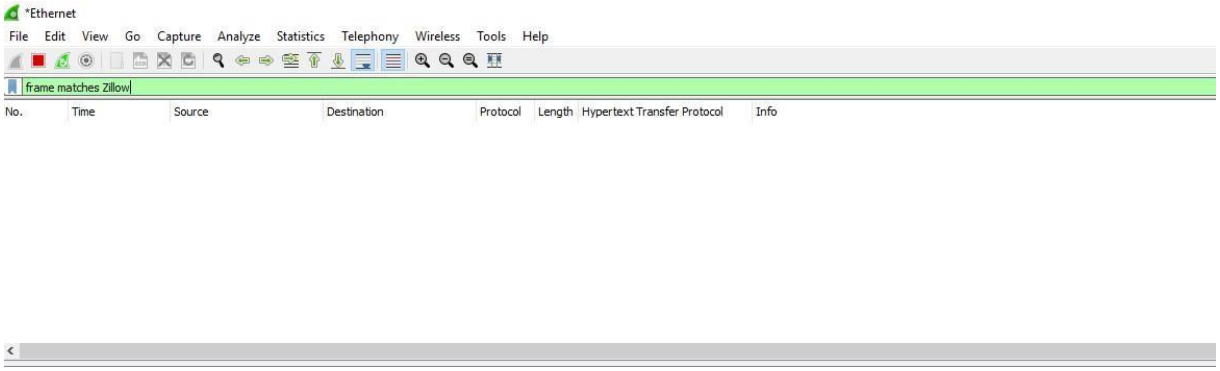
2. About what cell phone problem is the client concerned?

Analysis - Client talking about cell so we search for cell keyword in whole packets. We will use regular express for searching the cell keyword. Apply frame matches "(?!) cell" or frame matches cell.



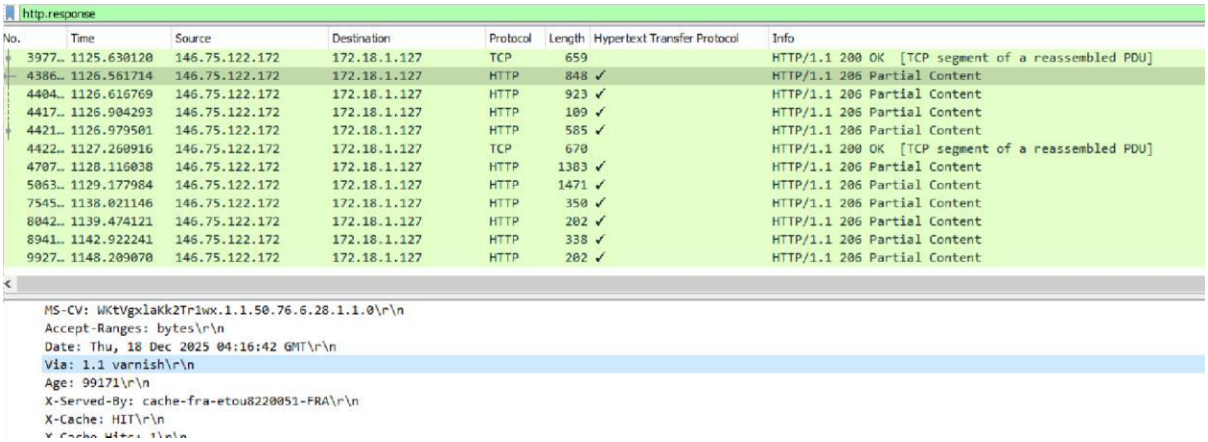
3. According to Zillow, what instrument will Ryan learn to play?

Analysis - As we did in the last challenge, we will apply a regular express filter for the Zillow keyword. Apply frame matched "(?!) zillow" or frame matches Zillow.

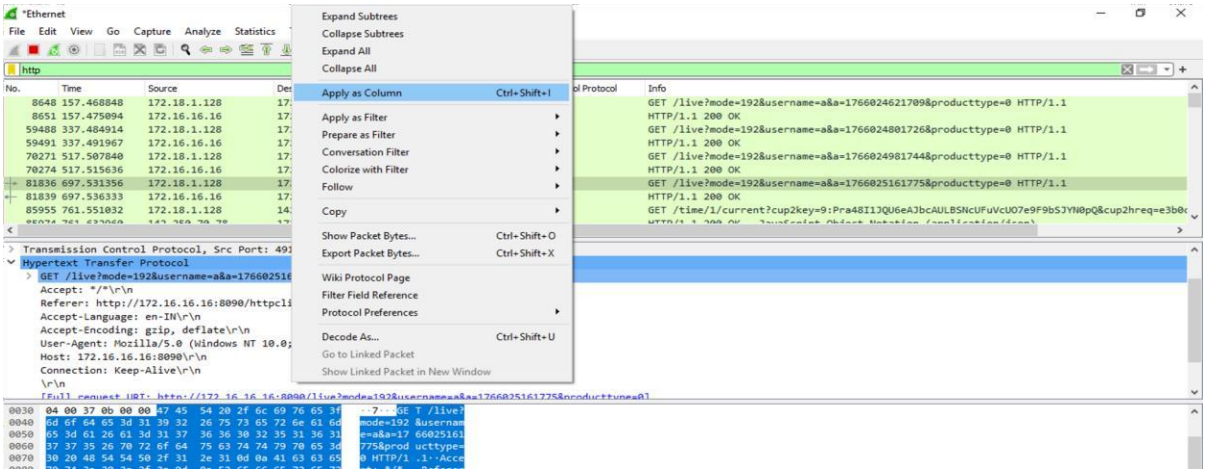


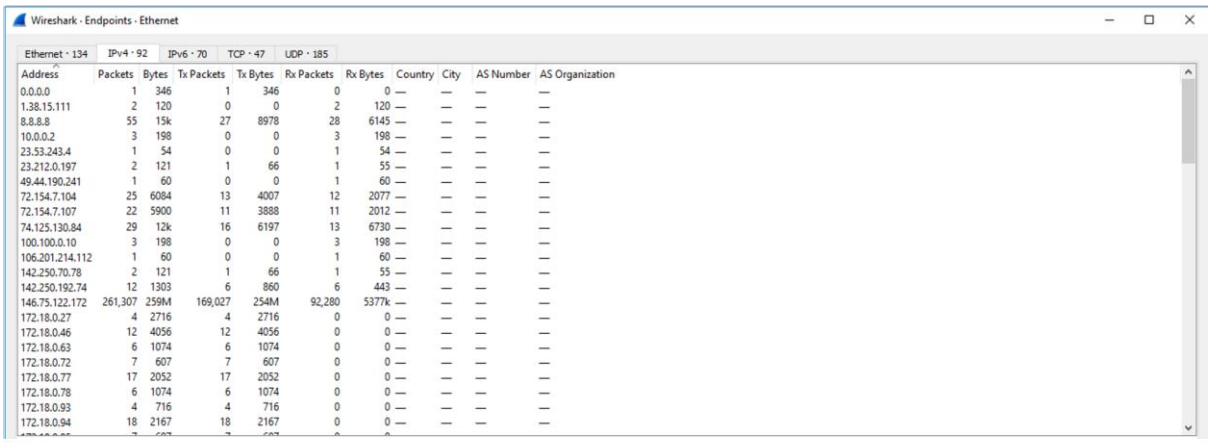
4. How many web servers are running Apache?

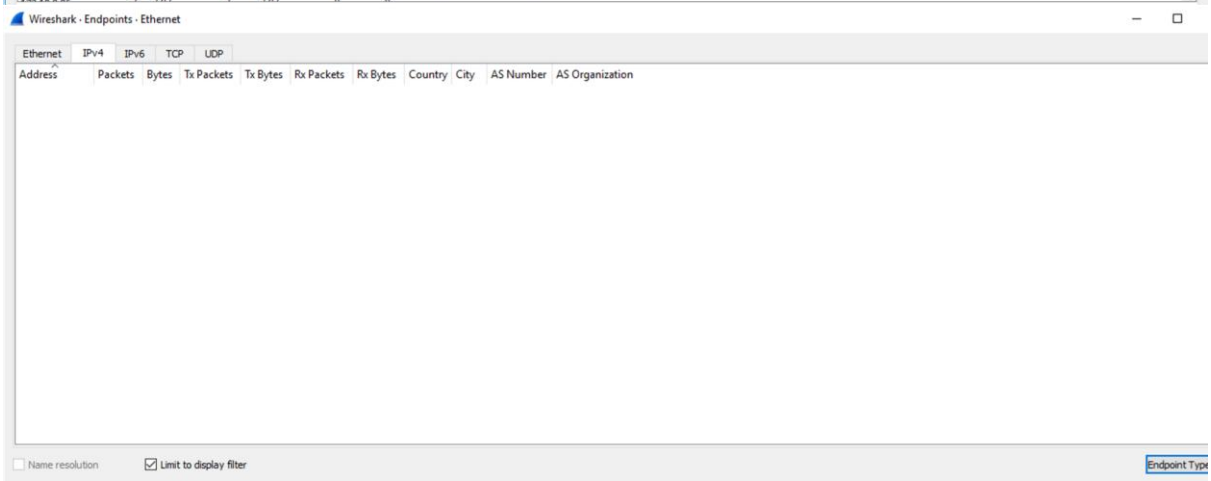
Analysis - The web server name can be retrieved from HTTP response header. So will apply filter http.response and we can see all http response packets.



Now, we will set the server header as column. Select any packet and right click on it and then select Apply as Column.







Now, we have to check how many Apache packets are there we can't count manually for each packet so we will apply another filter http.server contains "Apache"
